Table 1: DenseNet architectures for ImageNet. The growth rate for all the networks is $k = 32$. Note that each “conv” layer shown in the table corresponds the sequence BN-ReLU-Conv.

*“I have no idea how to come up with this!” –
John Langford, April 2018*

Motivation for Neural Architecture Search

- Model structure design is difficult.
 - Human experts have designed most networks till now.
 - Many data-sets without good priors on network design.
- Many models are similar to each other.
 - Hyper-parameter tuning is difficult.
 - Trying different architectures manually is difficult.
- Massive talent shortage!

15-minute literature overview

Neural Architecture Search

Search space?

- What architectures can be represented?
- Macro vs. Micro?
- How much human bias goes in search space design?

Search strategy?

- How to explore the search space?
- Classical explore-exploit problem
 - Want to find good architectures quickly.
 - Want to avoid premature convergence to suboptimal ones.

Performance estimation strategy?

- Find architectures that achieve high predictive performance on unseen data
- How do we estimate this performance?
- Can't simply perform standard training and validation (too expensive).
- Lots of research goes here.

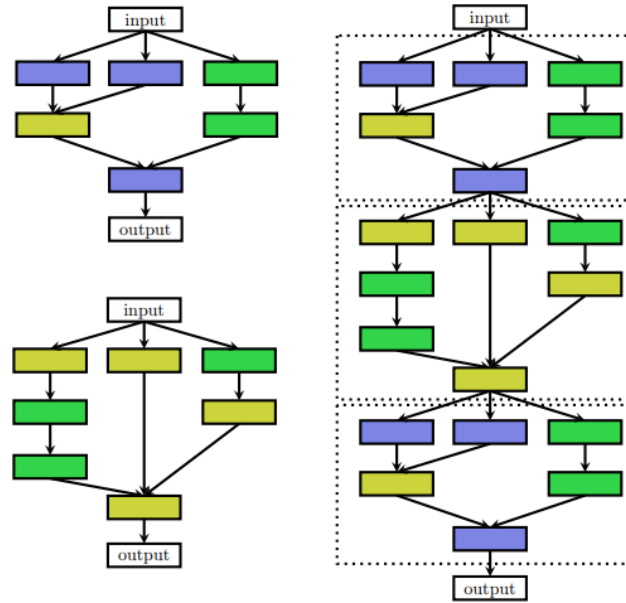

Figure 3: Illustration of the cell search space. Left: Two different cells, e.g., a normal cell (top) and a reduction cell (bottom) (Zoph et al., 2018). Right: an architecture built by stacking the cells sequentially. Note that cells can also be combined in a more complex manner, such as in multi-branch spaces, by simply replacing layers with cells.

Stack cells with predetermined skeletons. (Zoph et al., 2018)
 Domain knowledge injection for good skeletons needed.
 Our work shows lots of performance left on the table.

Figure 2: An illustration of different architecture spaces. Each node in the graphs corresponds to a layer in a neural network, e.g., a convolutional or pooling layer. Different layer types are visualized by different colors. An edge from layer L_i to layer L_j denotes that L_i receives the output of L_j as input. Left: an element of a chain-structured space. Right: an element of a more complex search space with additional layer types and multiple branches and skip connections.

General search space.

Little restriction on the kind of architectures that can be realized.

Can be hard to search due to size of space.

Neural Architecture
Search with
Reinforcement Learning
(Zoph and Le, 2016)

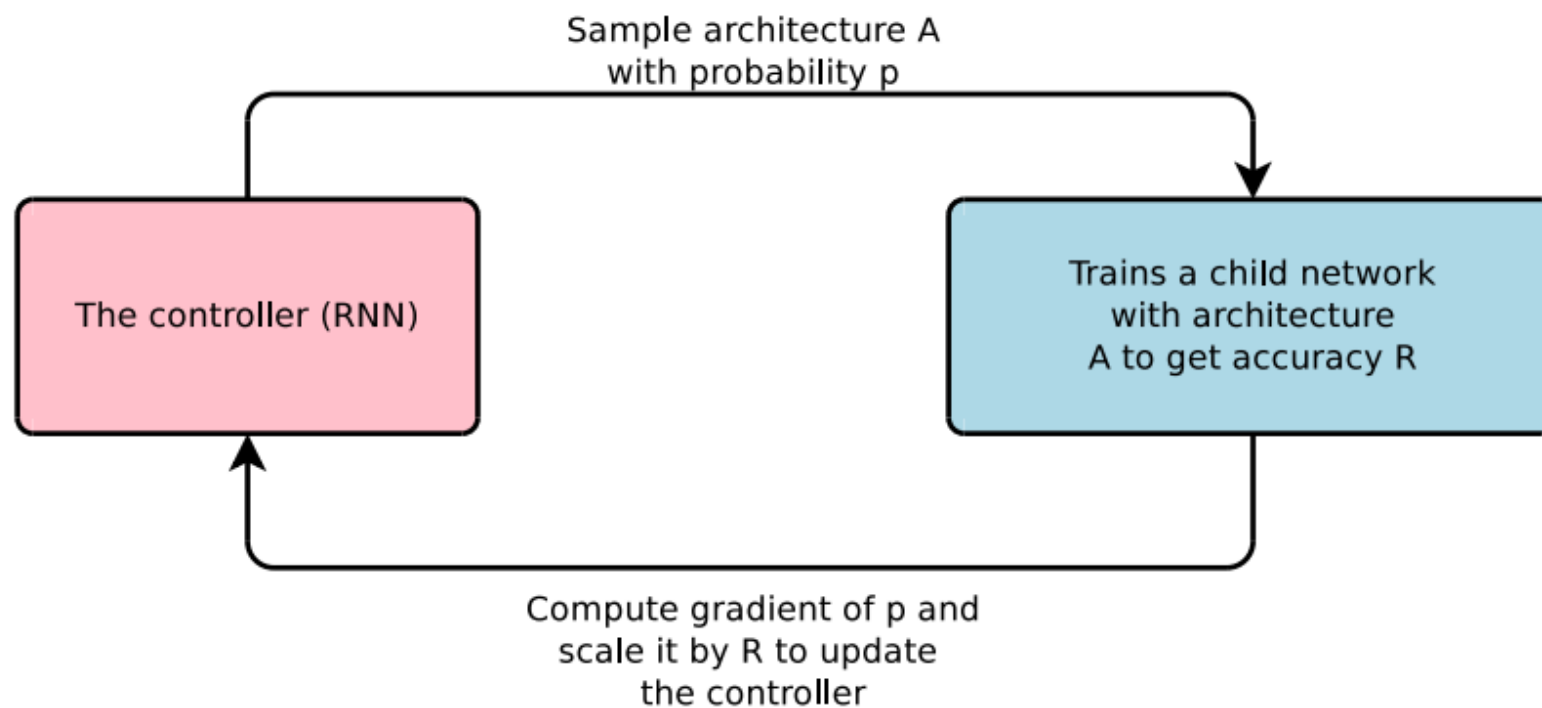

Figure 1: An overview of Neural Architecture Search.

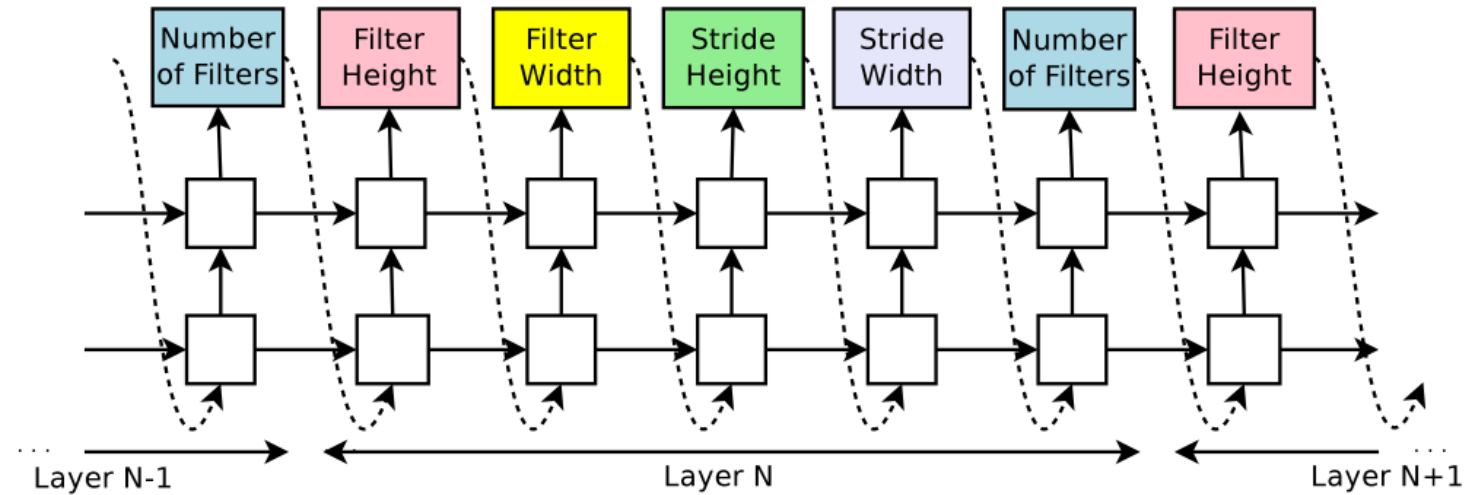

Figure 2: How our controller recurrent neural network samples a simple convolutional network. It predicts filter height, filter width, stride height, stride width, and number of filters for one layer and repeats. Every prediction is carried out by a softmax classifier and then fed into the next time step as input.

Efficient Neural
Architecture Search via
Parameter Sharing
(Pham et al, 2018)

ENAS

On CIFAR-10 achieves a test error of 2.89%

On Penn Treebank achieves perplexity of 55.8 (NAS had 62.4)

In all experiments used a single Nvidia 1080Ti GPU

Search takes less than 16 hours

Compared to NAS >1000x reduction in search time

The main contribution of this work is to improve the efficiency of NAS by forcing all child models to share weights to eschew training each child model from scratch to convergence.

Figure 2. The graph represents the entire search space while the red arrows define a model in the search space, which is decided by a controller. Here, node 1 is the input to the model whereas nodes 3 and 6 are the model's outputs.

Recurrent cell sampling

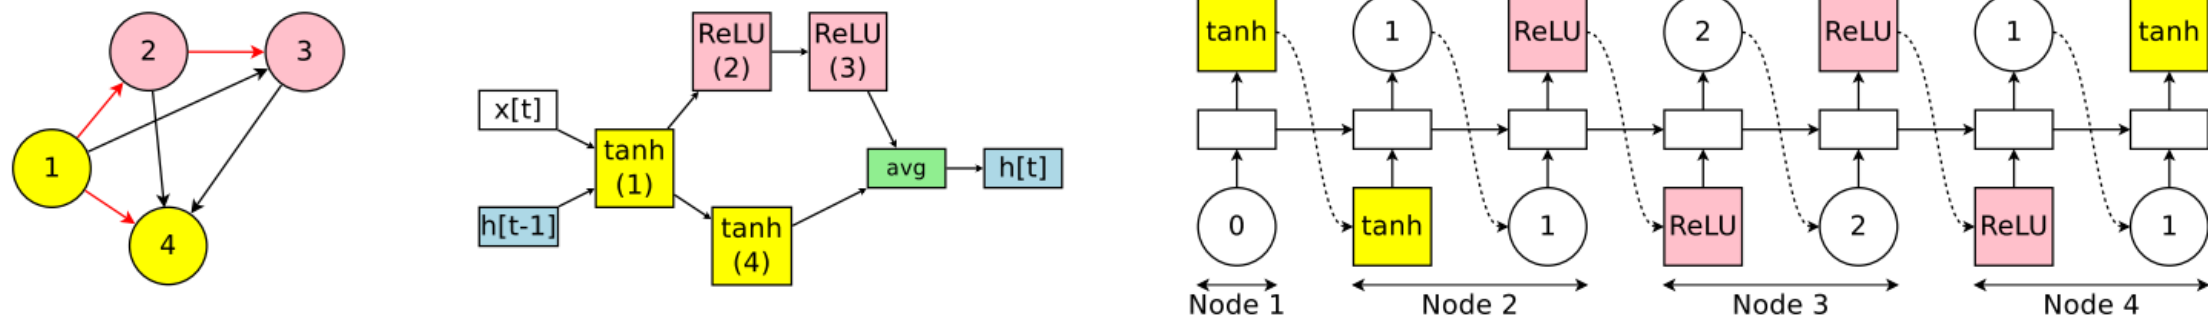

Figure 1. An example of a recurrent cell in our search space with 4 computational nodes. *Left:* The computational DAG that corresponds to the recurrent cell. The red edges represent the flow of information in the graph. *Middle:* The recurrent cell. *Right:* The outputs of the controller RNN that result in the cell in the middle and the DAG on the left. Note that nodes 3 and 4 are never sampled by the RNN, so their results are averaged and are treated as the cell's output.

Convolutional cell sampling

Figure 4. Connecting 3 blocks, each with N convolution cells and 1 reduction cell, to make the final network.

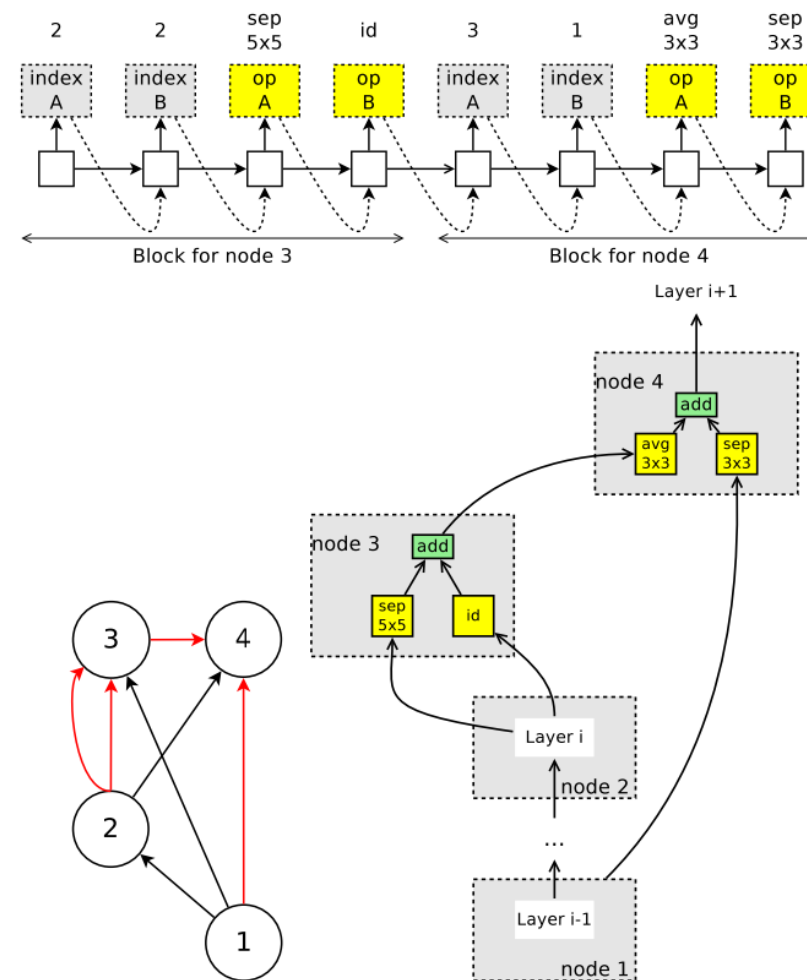

Figure 5. An example run of the controller for our search space over convolutional cells. *Top*: the controller's outputs. In our search space for convolutional cells, node 1 and node 2 are the cell's inputs, so the controller only has to design node 3 and node 4. *Bottom Left*: The corresponding DAG, where red edges represent the activated connections. *Bottom Right*: the convolutional cell according to the controller's sample.

Method	GPUs	Times (days)	Params (million)	Error (%)
DenseNet-BC (Huang et al., 2016)	—	—	25.6	3.46

Table 2. Classification errors of ENAS and baselines on CIFAR-10. In this table, the first block presents DenseNet, one of the state-of-the-art architectures designed by human experts. The second block presents approaches that design the entire network. The last block presents techniques that design modular cells which are combined to build the final network.

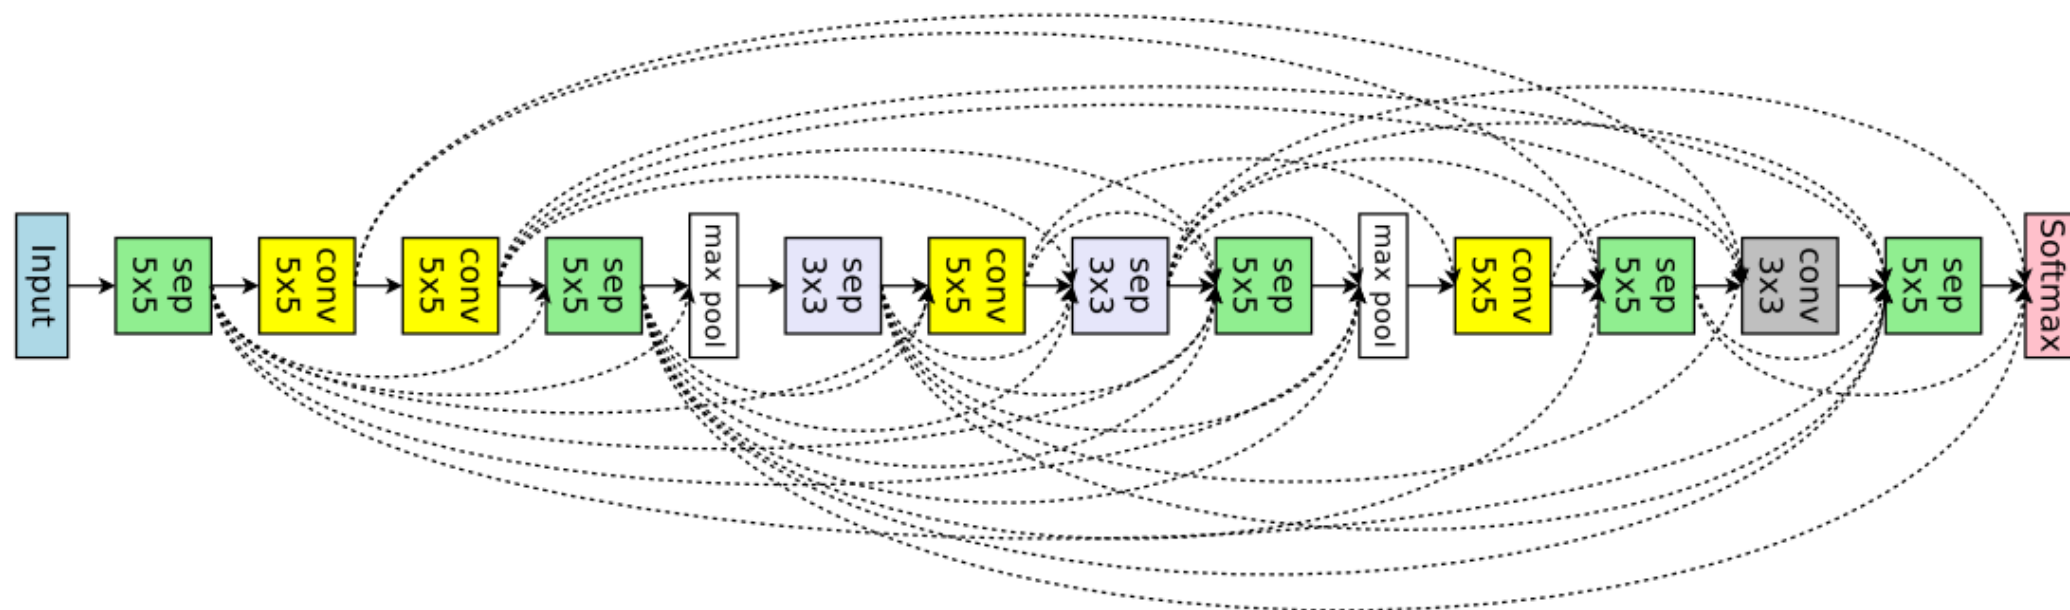

Figure 7. ENAS's discovered network from the macro search space for image classification.

Figure 8. ENAS cells discovered in the micro search space.

DARTS: Differentiable
Architecture Search
(Liu et al. 2018)

DARTS

- No controllers!
- No performance prediction!
- Outperforms ENAS, PNAS.
- Cell-based (micro).
- Achieves 2.83% error on CIFAR-10.
- Uses 1000x less computation than Regularized Evolution.

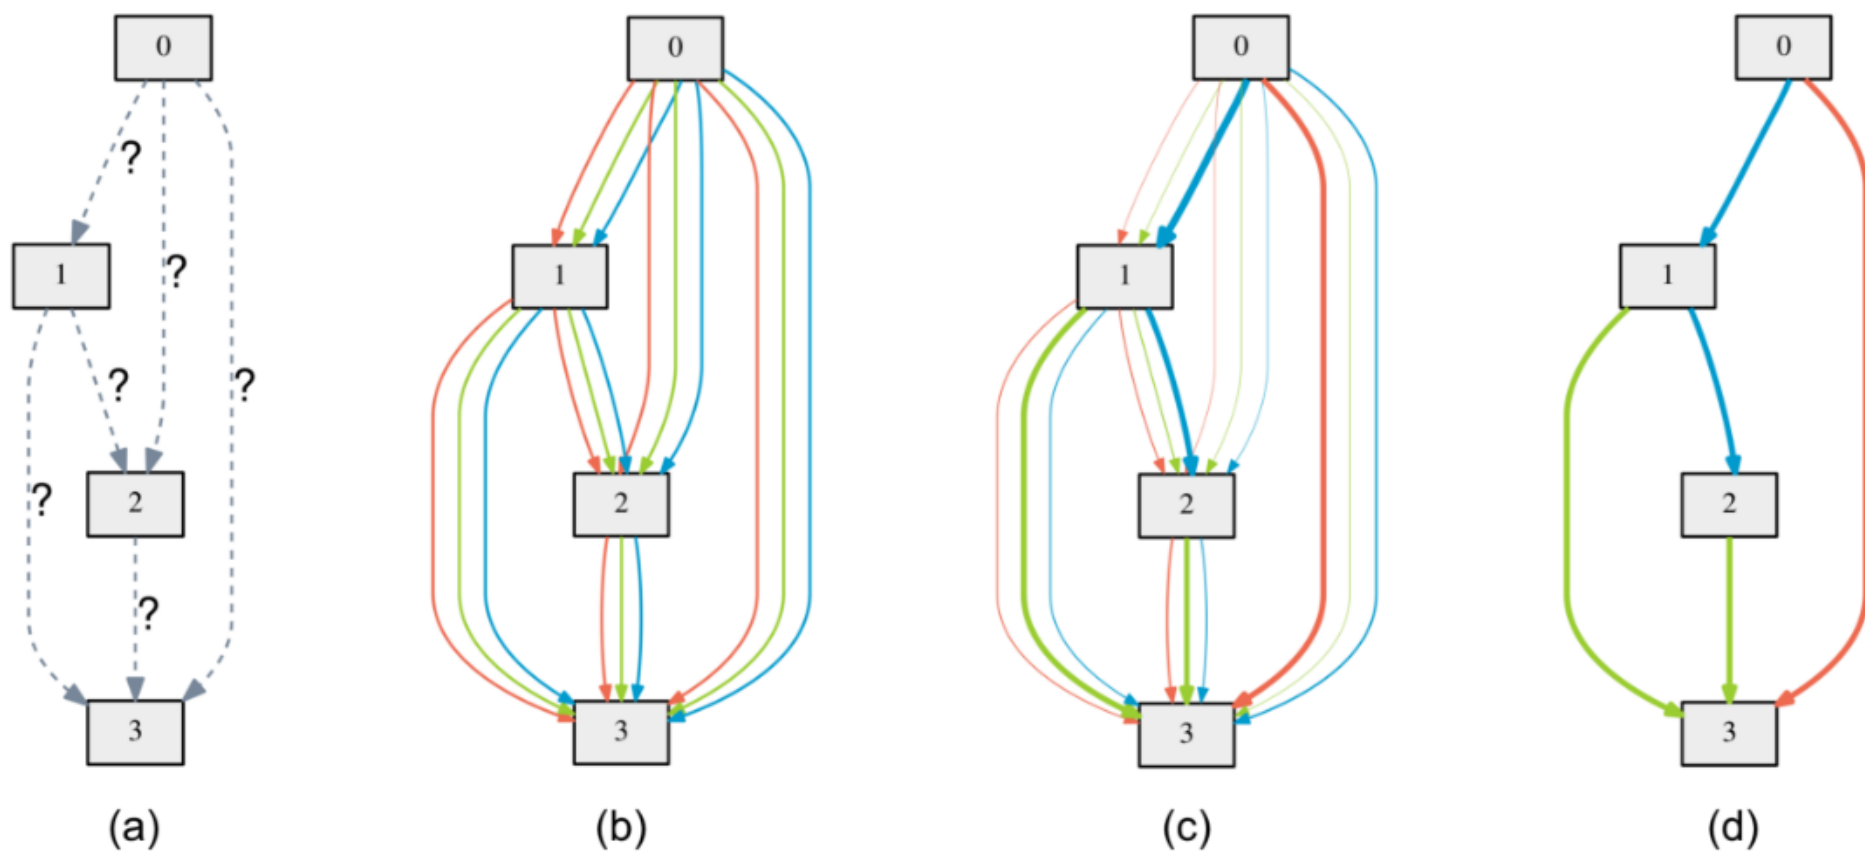

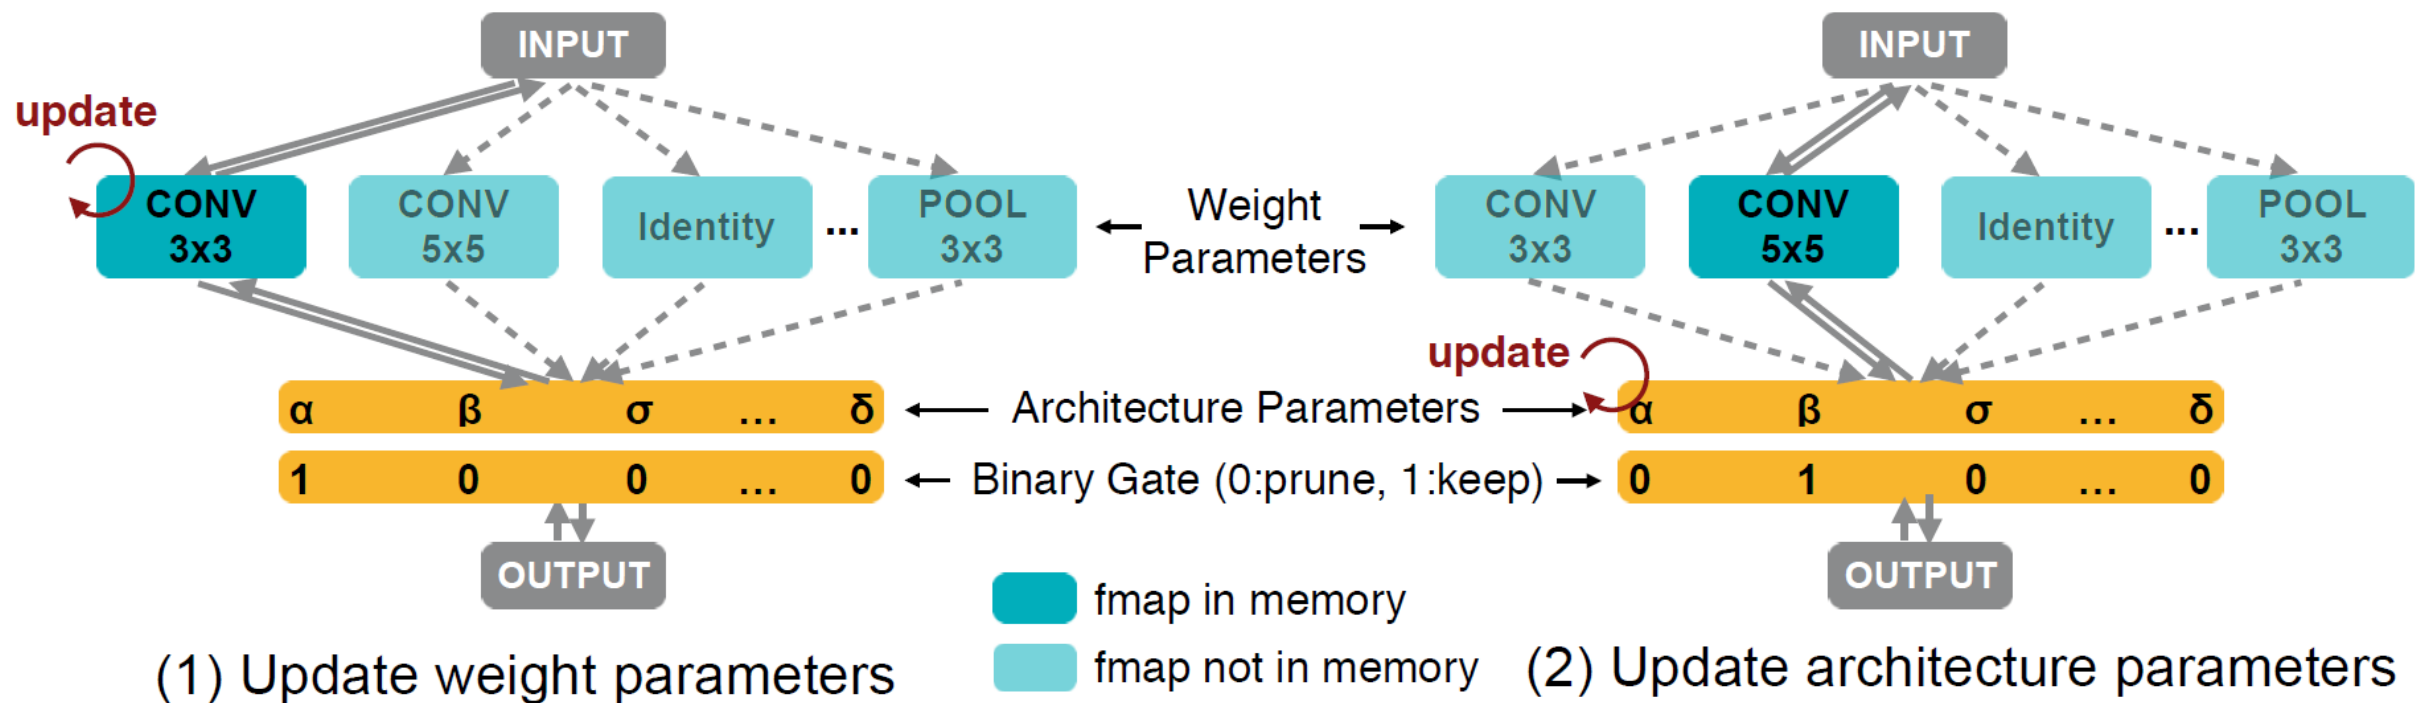

Figure 1: An overview of DARTS: (a) Operations on the edges are initially unknown. (b) Continuous relaxation of the search space by placing a mixture of candidate operations on each edge. (c) Joint optimization of the mixing probabilities and the network weights by solving a bilevel optimization problem. (d) Inducing the final architecture from the learned mixing probabilities.

ProxylessNas: Direct
Neural Architecture
Search on Target Task
and Hardware
(Cai et al. 2018)

Fixes the memory problems in DARTS

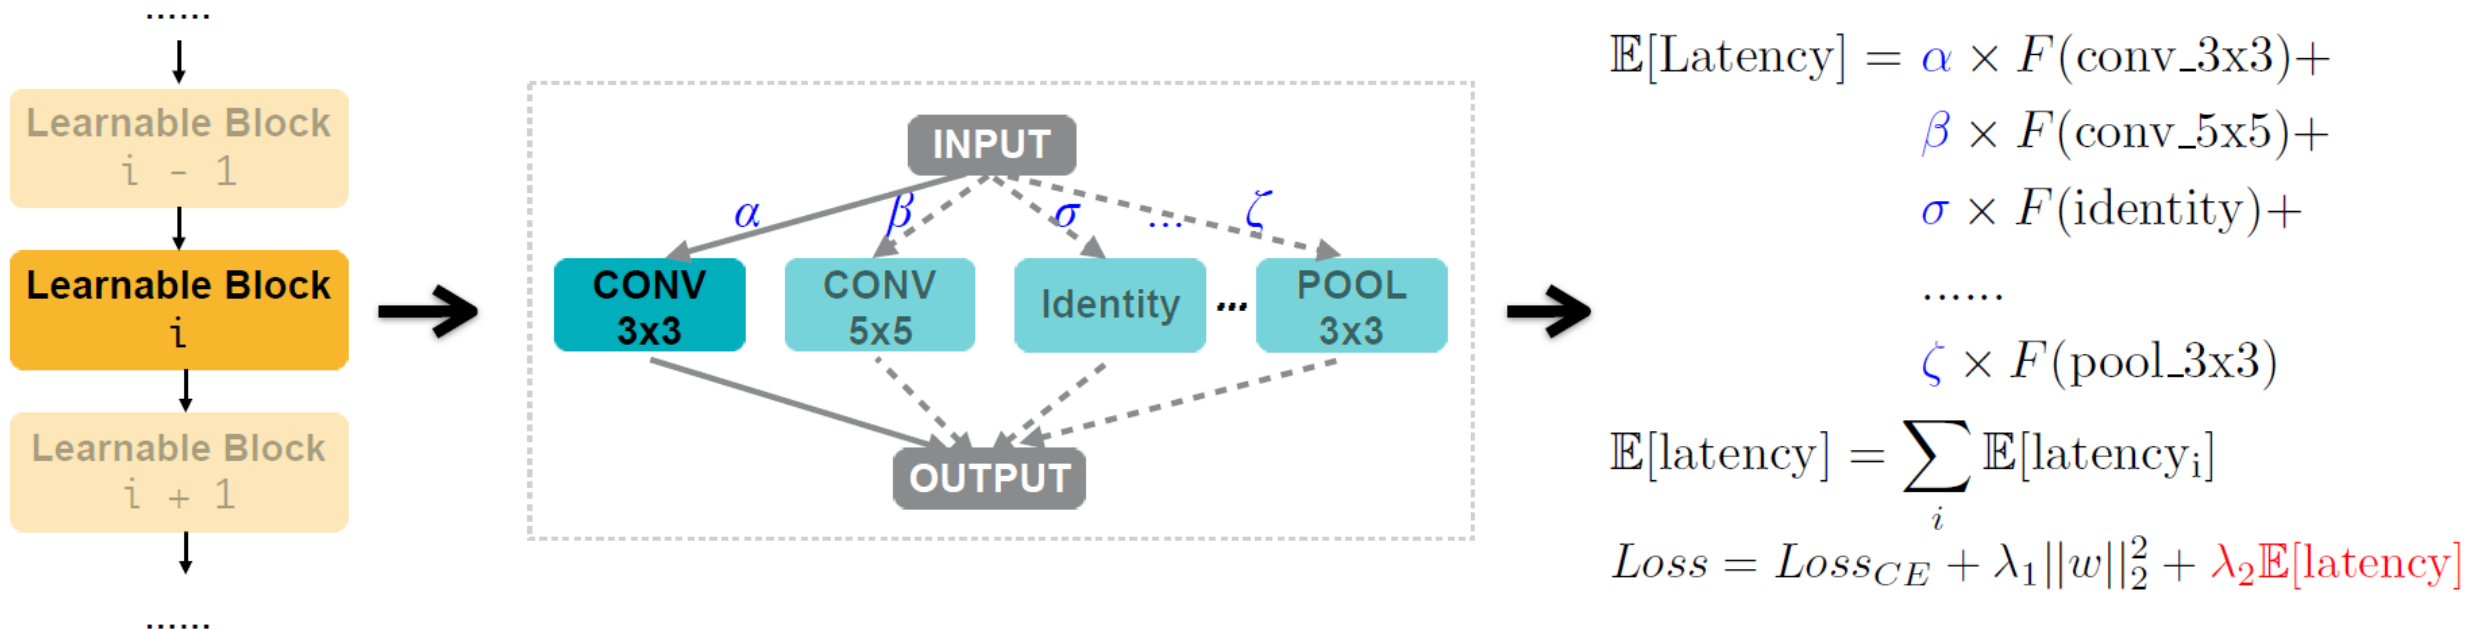

Figure 3: Making latency differentiable by introducing latency regularization loss.

Model	Top-1	Top-5	Mobile Latency	Hardware-aware	No Proxy	No Repeat	Search cost (GPU hours)
MobileNetV1 [16]	70.6	89.5	113ms	-	-	\times	Manual
MobileNetV2 [28]	72.0	91.0	75ms	-	-	\times	Manual
NASNet-A [34]	74.0	91.3	183ms	\times	\times	\times	48,000
AmoebaNet-A [27]	74.5	92.0	190ms	\times	\times	\times	75,600
MnasNet [29]	74.0	91.8	76ms	\checkmark	\times	\times	40,000
MnasNet (our impl.)	74.0	91.8	79ms	\checkmark	\times	\times	40,000
Proxyless-G (mobile)	71.8	90.3	83ms	\times	\checkmark	\checkmark	200
Proxyless-G + LL	74.2	91.7	79ms	\checkmark	\checkmark	\checkmark	200
Proxyless-R (mobile)	74.6	92.2	78ms	\checkmark	\checkmark	\checkmark	200

Table 2: ProxylessNAS achieves state-of-the-art accuracy (%) on ImageNet (under mobile latency constraint $\leq 80ms$) with $200\times$ less search cost in GPU hours. “LL” indicates latency regularization loss. Details of MnasNet’s search cost are provided in appendix C.

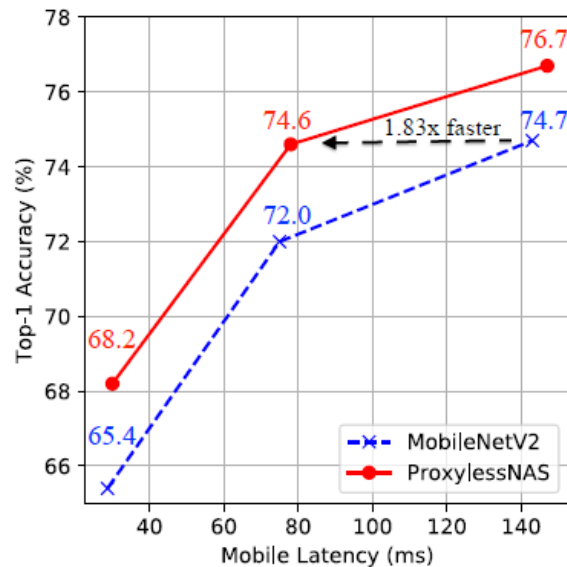

Figure 4: ProxylessNAS consistently outperforms MobileNetV2 under various latency settings.

Figure 5: Our mobile latency model is close to $y = x$. The latency RMSE is 0.75ms.

DARTS Problems

(a) Space 1

(b) Space 2

(c) Space 3

(d) Space 4

Figure 1: The poor cells standard DARTS finds on spaces S1-S4. For all spaces, DARTS chooses mostly parameter-less operations (skip connection) or even the harmful *Noise* operation. Shown are the normal cells on CIFAR-10; see Appendix G for reduction cells and other datasets.

DARTS Problems

Figure 2: Test regret and validation error of the one-shot model when running DARTS on S5 and CIFAR-10. DARTS finds the global minimum but starts overfitting the architectural parameters to the validation set in the end.

Figure 3: (*Left*) validation error of search model; (*Middle*) Test error of the architectures deemed by DARTS optimal at the end of every 5 epochs; (*Right*) Dominant eigenvalue of $\nabla_{\alpha}^2 \mathcal{L}_{valid}$ throughout DARTS search. The solid line and shaded areas show the mean and standard deviation of 3 independent search runs. All experiments were conducted on CIFAR-10.

Figure 15: Correlation between the average (across search epochs) dominant eigenvalue of $\nabla_{\alpha}^2 \mathcal{L}_{valid}$ and the test error of architectures.

DARTS Problems: Fix 1

To implement this idea, we propose a simple heuristic that worked off-the-shelf without the need for any tuning. Let $\bar{\lambda}_{max}^{\alpha}(i)$ denote the value of λ_{max}^{α} smoothed over $k = 5$ epochs around i ; then, we stop if $\bar{\lambda}_{max}^{\alpha}(i - k) / \bar{\lambda}_{max}^{\alpha}(i) < 0.75$ and return the architecture from epoch $i - k$. By this early

Table 1: Performance of architectures found by DARTS vs. DARTS-ES. For each of the settings we repeat the search 3 times and report the mean \pm std (median) of the 3 found architectures retrained from scratch.

Setting		DARTS	DARTS-ES
C10	S1	4.66 \pm 0.71 (4.57)	3.05 \pm 0.07 (3.01)
	S2	4.42 \pm 0.40 (4.52)	3.41 \pm 0.14 (3.39)
	S3	4.12 \pm 0.85 (3.73)	3.71 \pm 1.14 (3.07)
	S4	6.95 \pm 0.18 (6.86)	4.17 \pm 0.21 (4.24)
C100	S1	29.93 \pm 0.41 (29.88)	28.90 \pm 0.81 (28.37)
	S2	28.75 \pm 0.92 (28.31)	24.68 \pm 1.43 (24.03)
	S3	29.01 \pm 0.24 (28.90)	26.99 \pm 1.79 (25.20)
	S4	24.77 \pm 1.51 (24.92)	23.90 \pm 2.01 (23.89)
SVHN	S1	9.88 \pm 5.50 (7.60)	2.80 \pm 0.09 (2.76)
	S2	3.69 \pm 0.12 (3.73)	2.68 \pm 0.18 (2.62)
	S3	4.00 \pm 1.01 (3.47)	2.78 \pm 0.29 (2.65)
	S4	2.90 \pm 0.02 (2.91)	2.55 \pm 0.15 (2.51)

DARTS Problems

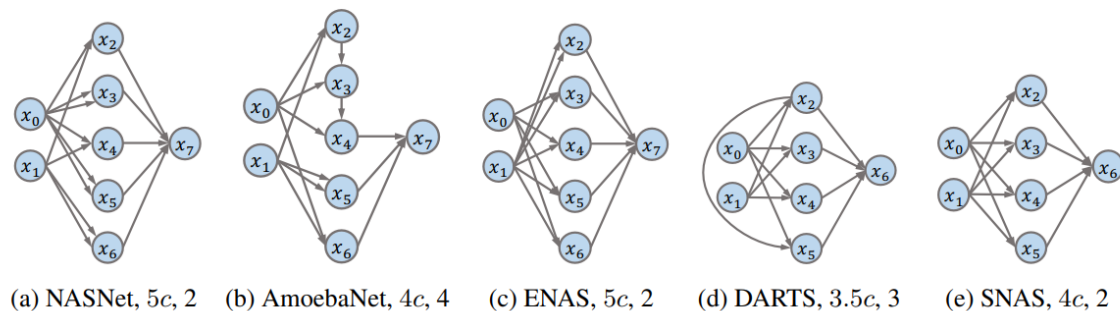

Figure 1: Topologies of cells from popular NAS architectures. Each sub-figure has three sets of nodes from left to right, which are the input nodes, intermediate nodes, and output node respectively. The arrows (i.e., operations of the cell) represent the direction of information flow. The caption of each sub-figure includes the name of the architecture, width and depth of a cell following our definition. The width of a cell is computed by assuming that all intermediate nodes share the same width c .

Figure 2: Topologies of DARTS (Liu et al., 2019) cell (leftmost) and its variants with random connections. The depth and width of cells are increasing and decreasing respectively from left to right. Namely, the original DARTS cell C^{darts} is the widest and shallowest one among these cells.

Motivation for Growing Networks

- Fully general method!
 - Cell-search not feasible when you don't know good outer skeleton!
- Lifelong learning models.
 - New task/extra or evolving data can be naturally incorporated.
 - Can accommodate larger models.
- Exploit prior knowledge when available.
 - Explore a forest of models.
 - Warm start from existing models.
 - Universal post-processing for human-designed models!
 - Exploit information from similar models during search.

Project Petridish

- An overview of neural architecture search
- Method
 - Warm start
 - Inspired by gradient boosting.
 - Expand the search tree:
 - Focus on the most cost-effective ones.
 - Directly search the pareto-frontier.
 - Predict performance.
 - Utilizing model initialization to select children to train.

The Cascade-Correlation Learning Architecture

Scott E. Fahlman and Christian Lebiere

August 29, 1991

CMU-CS-90-100

School of Computer Science
Carnegie Mellon University
Pittsburgh, PA 15213

Abstract

Cascade-Correlation is a new architecture and supervised learning algorithm for artificial neural networks. Instead of just adjusting the weights in a network of fixed topology, Cascade-Correlation begins with a minimal network, then automatically trains and adds new hidden units one by one, creating a multi-layer structure. Once a new hidden unit has been added to the network, its input-side weights are frozen. This unit then becomes a permanent feature-detector in the network, available for producing outputs or for creating other, more complex feature detectors. The Cascade-Correlation architecture has several advantages over existing algorithms: it learns very quickly, the network determines its own size and topology, it retains the structures it has built even if the training set changes, and it requires no back-propagation of error signals through the connections of the network.

Figure 1: The Cascade architecture, initial state and after adding two hidden units. The vertical lines sum all incoming activation. Boxed connections are frozen, X connections are trained repeatedly.

Incremental Training

Phase 0
Original model

Phase 1
Initialize candidates,
but do not allow candidates
to affect the original model.

Phase 2
Officially add an
candidate to model.
Now the candidate can
affect the original.

Incremental Training

Original model

Initialize candidate

Candidate accumulates $\nabla_B Loss$

Sum

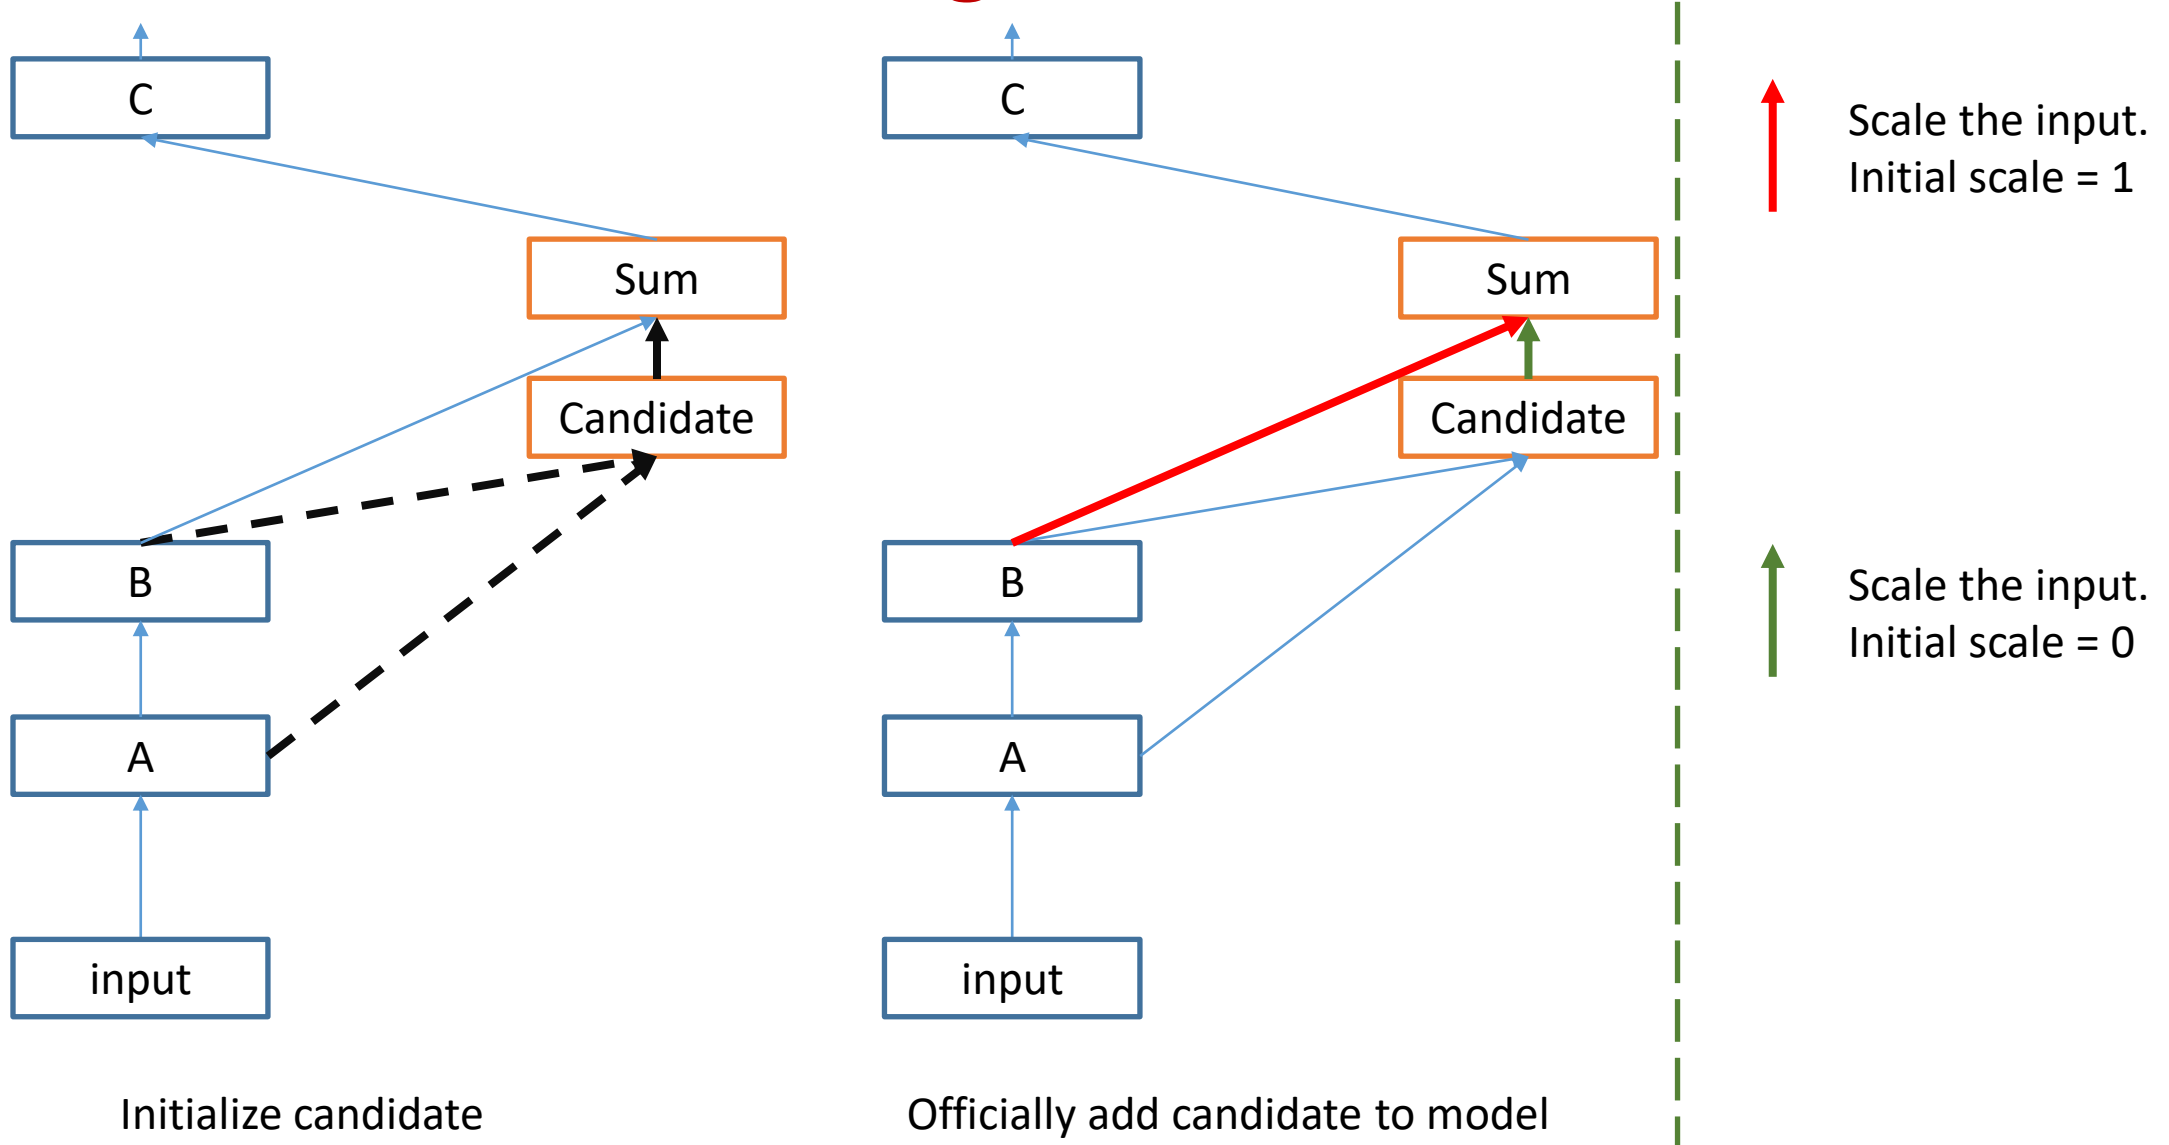

Candidate

Forward = zero
Backward = identity

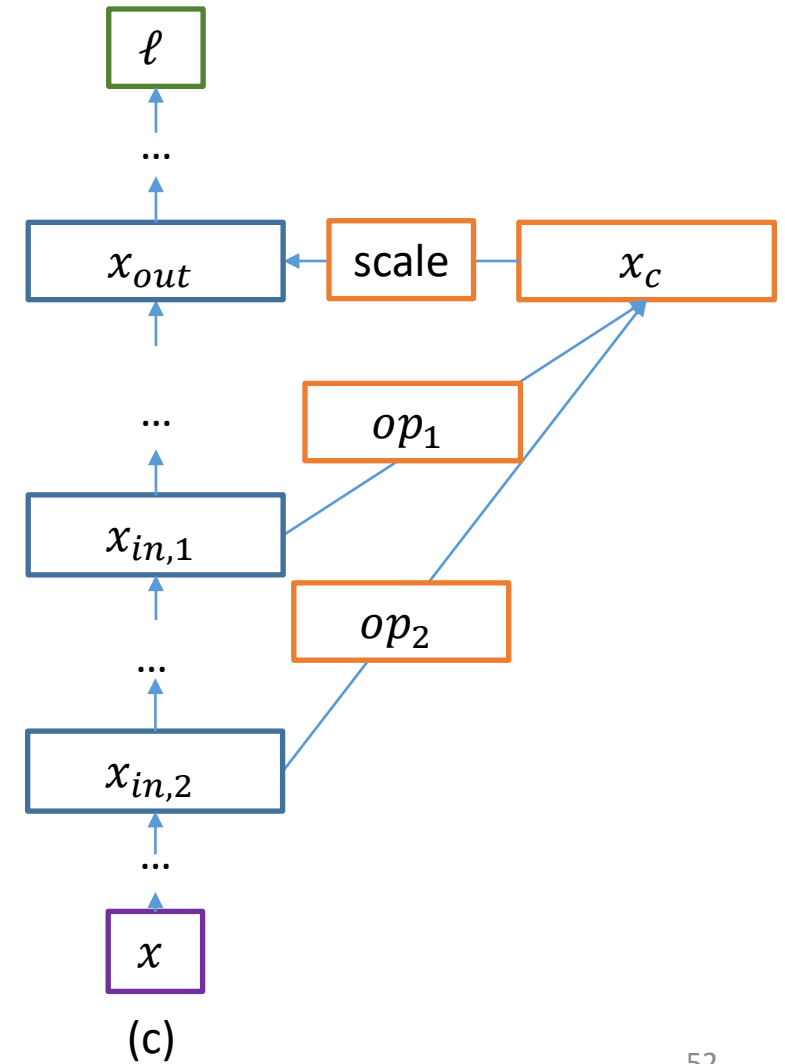

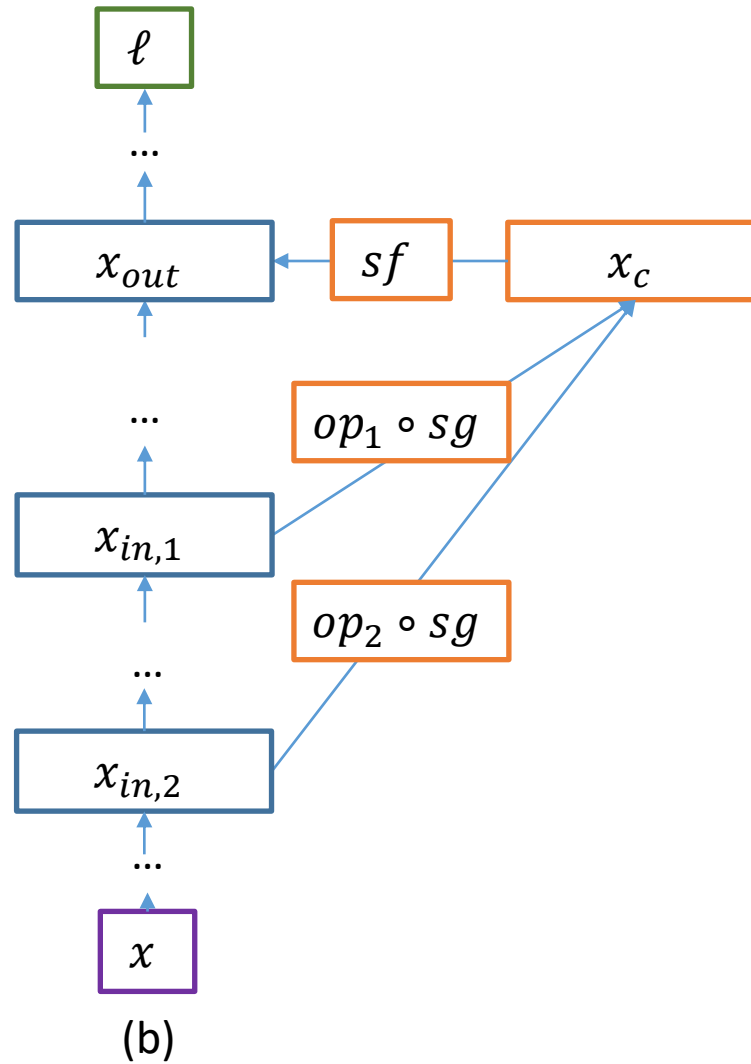

Forward = identity
Backward = zero

Regular edge:
Forward = identity
Backward = identity

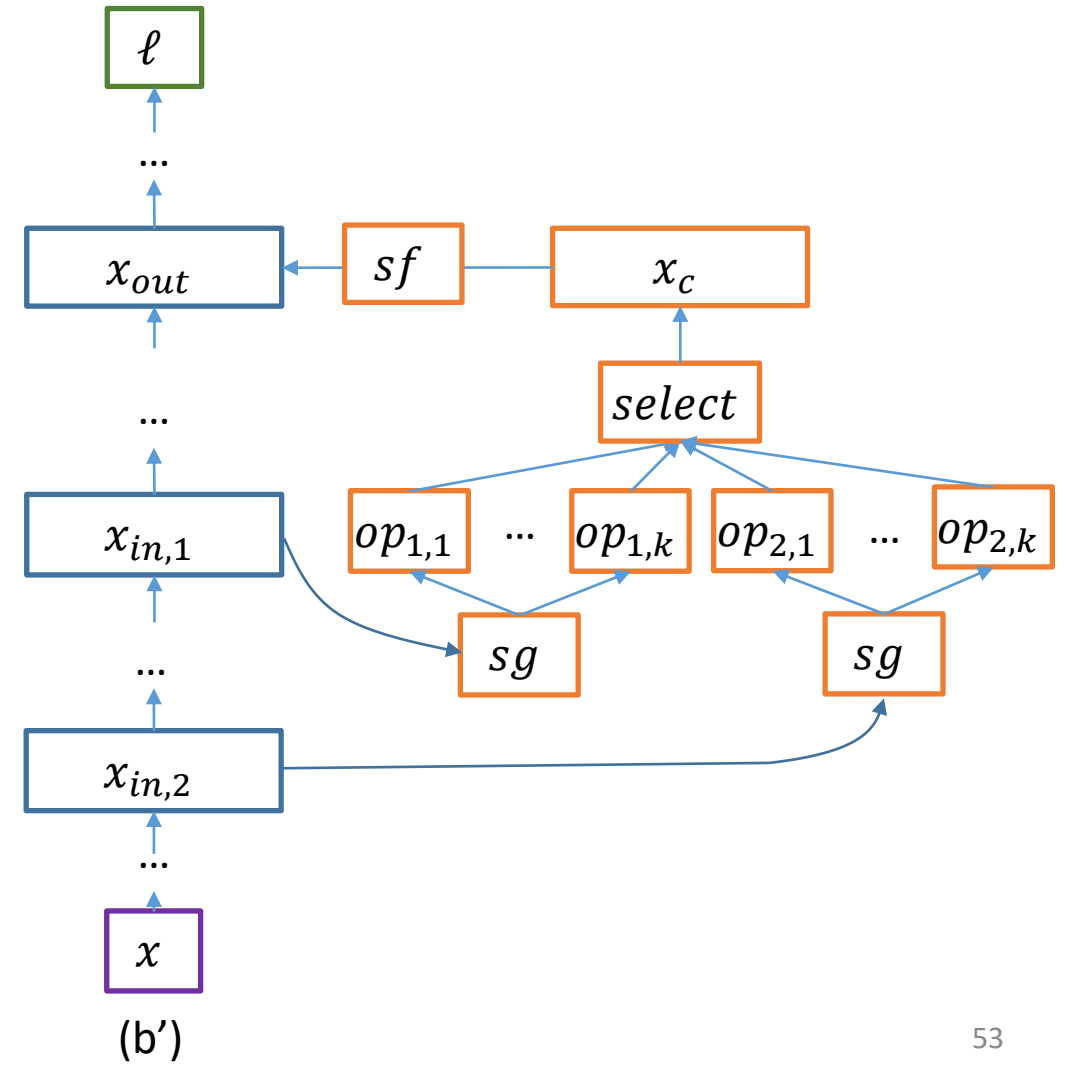

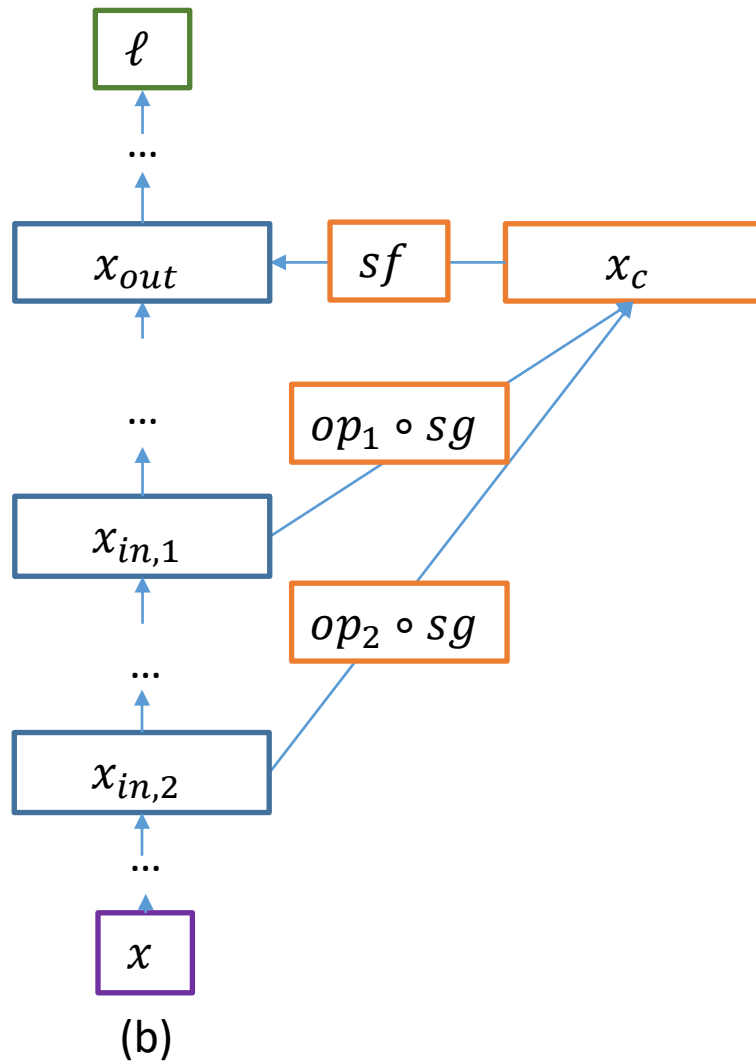

Incremental Training

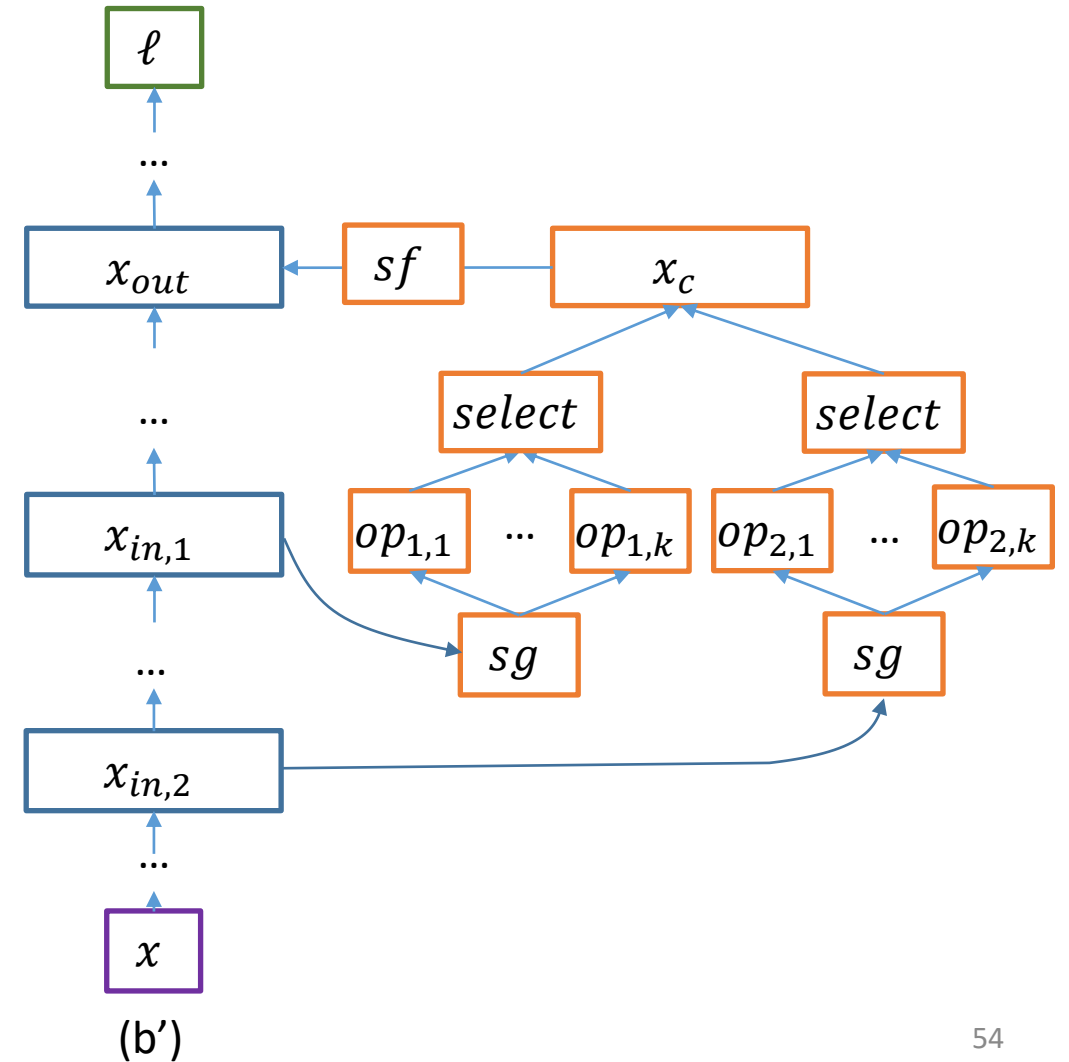

Incremental Training (Summary)

Incremental Training (Choice of Candidates)

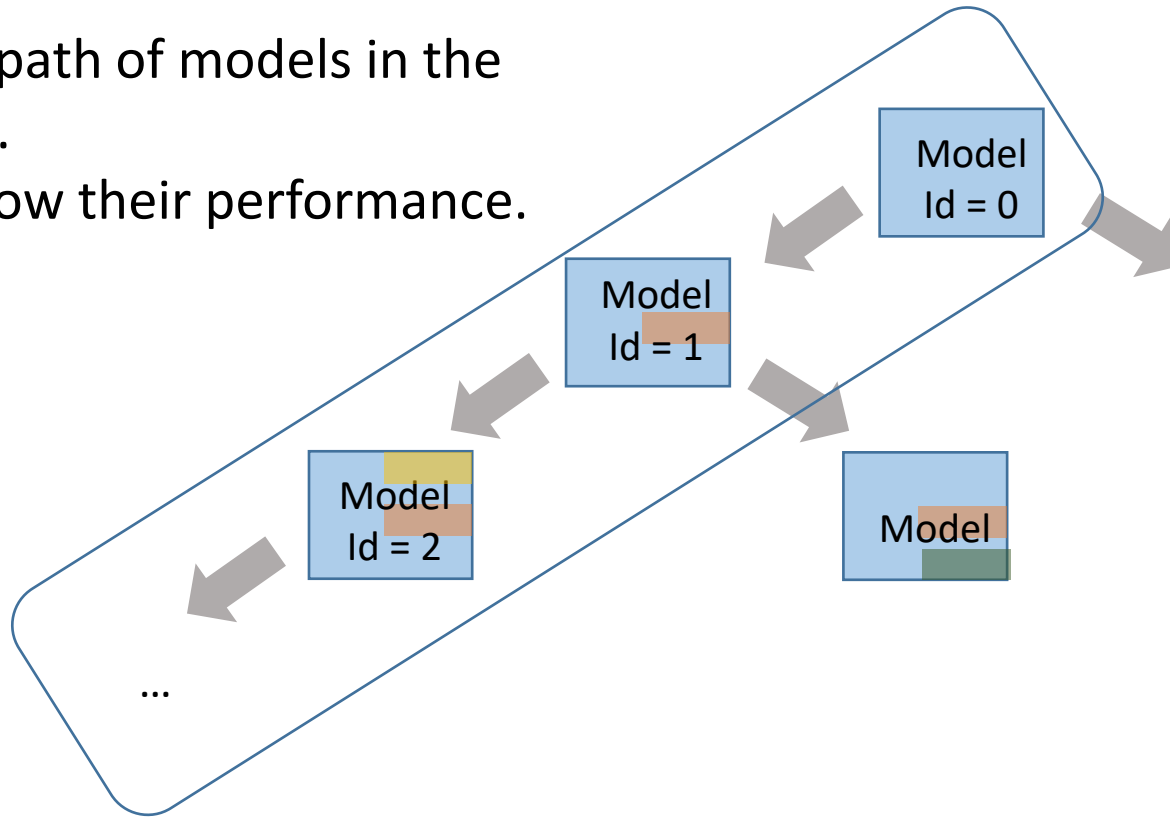

Incremental Training (Choice of Candidates)

Incremental training during search

Consider a path of models in the search tree.
Want to know their performance.

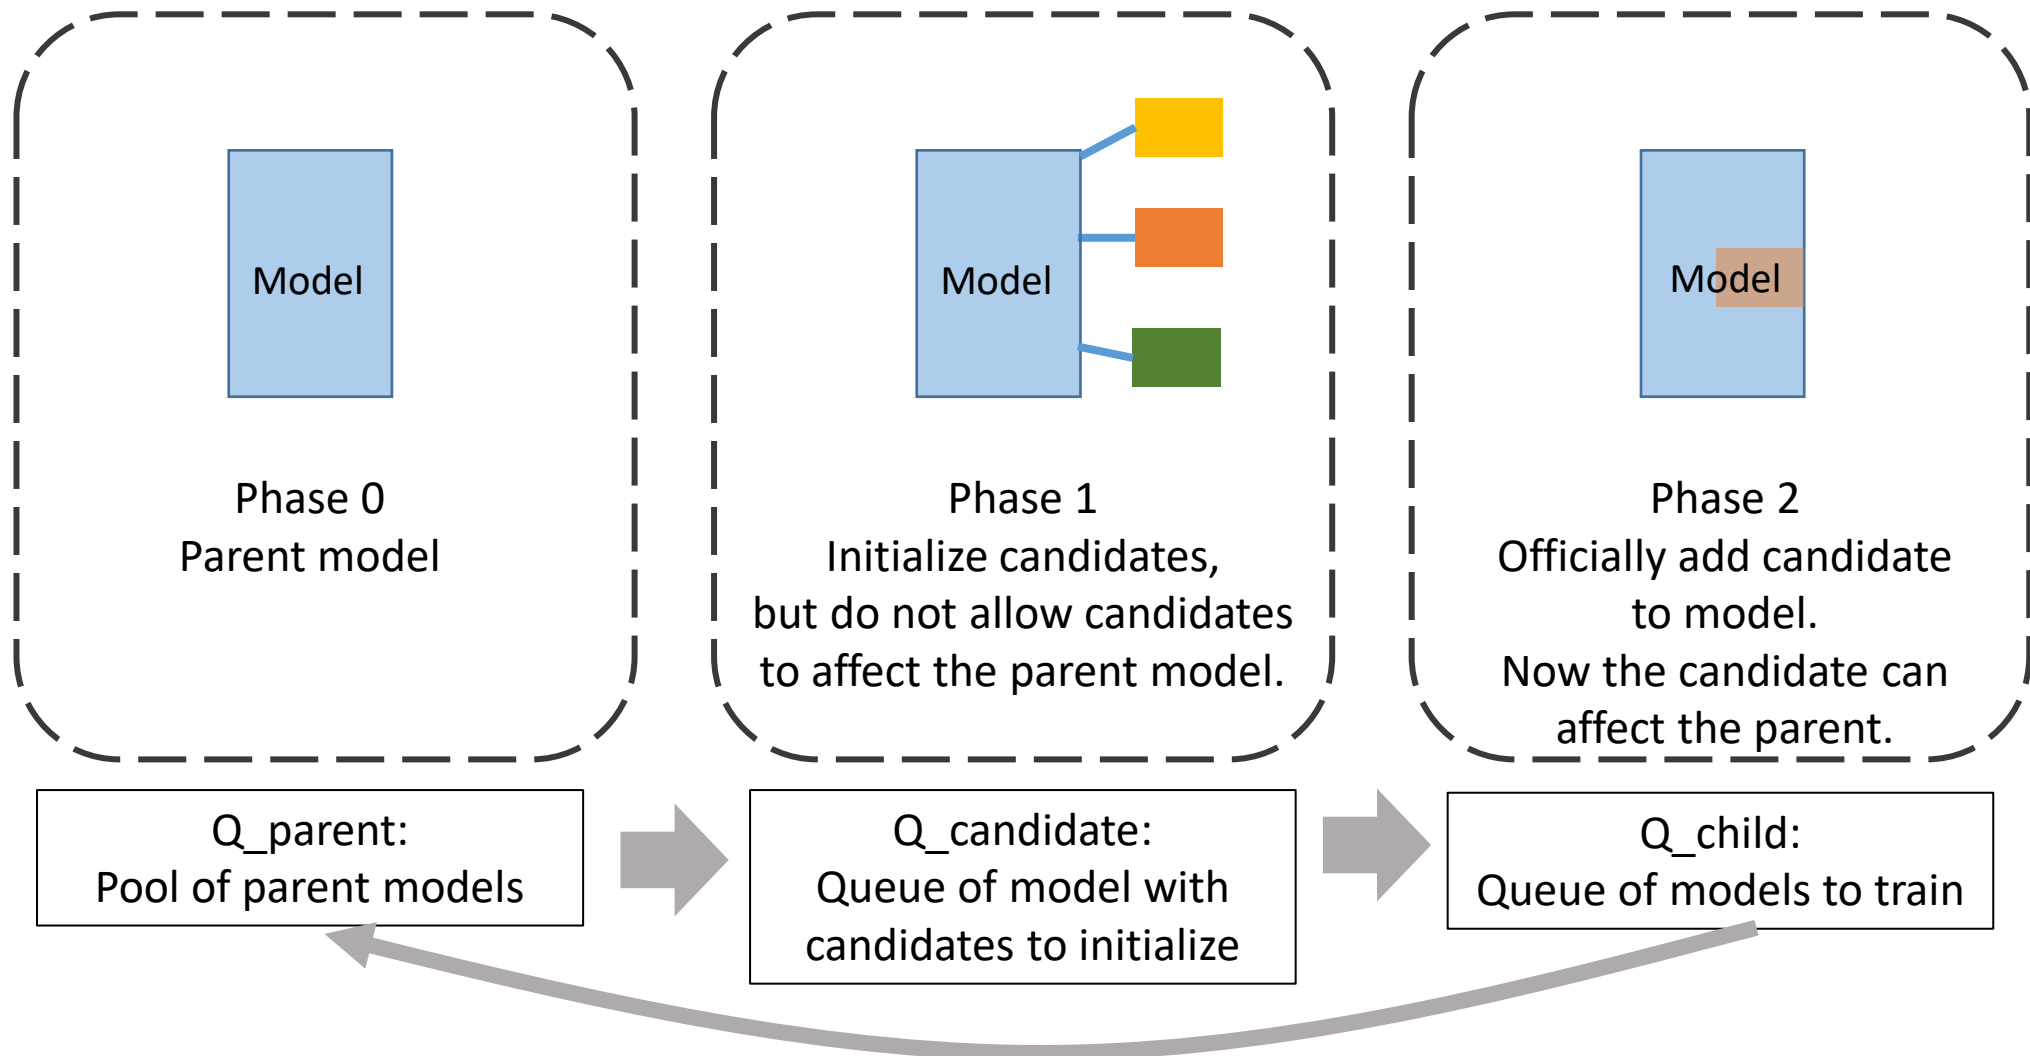

Option 1 (From-scratch) :

- Train models independently.
- 300 epochs per model

Option 2 (Incremental) :

- Start from parent; initialize children
- 40 epochs per model

Search on distributed systems

Search on distributed systems

- Q_parent: explore-exploit a diverse set of good models to extend.
 - Q_candidate: initialize promising candidates
 - Q_children: train promising children
-
- How do we know a model is good?

Expanding the Most Cost-efficient Models

This figure is for
illustration only

Expanding the Most Cost-efficient Models

- Convex hull

Expanding the Most Cost-efficient Models

- Epsilon-convex hull

Key advantage:

Method naturally produces a 'gallery' of models which are nearly-optimal for every serving time budget need.

This is critical to production serving needs.

Results

Reproducibility and fair comparison crisis!

- Nearly impossible to compare algorithms due to differences in
 - Search spaces
 - Training routine used (does it have all the tips and tricks?)
 - Hardware used (TPU vs. GPU vs. driver version vs. cuda version vs.....)
 - Stochasticity in training on gpus.
- Community working to establish standard benchmark
 - [NASBench-101](#)
 - Cannot evaluate weight-sharing, DARTS-like search spaces
 - [NASBench-201](#)
 - Uses different search space than 101.
 - [NASBench-1Shot1](#)
 - Leverages 101 to make it amenable for weight-sharing

Table 1: Comparison against state-of-the-art recognition results on CIFAR-10. Results marked with \dagger are not trained with cutout. The first block represents approaches for macro-search. The second block represents approaches for cell-search. We report Petridish results in the format of “best | mean \pm standard deviation” among five repetitions of the final training.

Method	# params (mil.)	Search (GPU-Days)	Test Error (%)

Petridish cell (N=6,F=44)	4.8	598	5	26.0

No domain-knowledge injection in
architecture design at all!

Language Modeling

Table 9: Comparison against state-of-the-art language modeling results on PTB. We report Petridish results in the format of “best | mean \pm standard deviation” from 10 repetitions of the search with different random seeds. * From Table 2 in (Li & Talwalkar, 2019). † (Li & Talwalkar, 2019) report being unable to reproduce the DARTS results and this entry represents the results of DARTS (second order) as obtained via their deterministic implementation. ** (Li & Talwalkar, 2019) report being unable to reproduce ENAS results from original source code. *** ENAS results as reproduced via DARTS source code.

Method	# params (M)	Search (GPU-Days)	Test Error (perplexity)
Darts (first order) (Liu et al., 2019)*	23	1.5	57.6
Darts (second order) (Liu et al., 2019)*	23	2	55.7
Darts (second order) (Liu et al., 2019)* †	23	2	55.9
ENAS (Pham et al., 2018)**	24	0.5	56.3
ENAS (Pham et al., 2018)***	24	0.5	58.6
Random search baseline (Li & Talwalkar, 2019)*	23	2	59.4
Random search WS (Li & Talwalkar, 2019)*	23	1.25	55.5
Petridish	23	1	55.85 56.39 \pm 0.38

Note that since random search is essentially state-of-the-art search algorithm on PTB, we caution the community to not use PTB as a benchmark for comparing search algorithms for RNNs. The merits of any particular algorithm are difficult to compare at least on this particular dataset and task pairing. More research along the lines of Ying et al. (2019) is needed on 1. whether the nature of the search space for RNNs specific to language modeling is particularly amenable to random search and or 2. whether it is the specific nature of RNNs by itself such that random search is competitive on any task which uses RNNs as the hypothesis space. We are presenting the results on PTB for the sake of completion since it has become one of the default benchmarks but ourselves don't derive any particular signal either way in spite of competitive performance.

*Is AutoML
solved?*

Still lots of domain knowledge injection into the process.

Tricks and tips needed for vision datasets are completely different from language or speech datasets (to be SOTA).

Need better benchmarks and more rigorous reporting.

Majority papers currently report on CIFAR10/100, ImageNet, PennTree Bank.

Hyperparameters are set to magic constants.

No fully general solution yet but
useful successes!

Beyond Op Selection

ARCHAI

ETA: June 2020

<https://github.com/microsoft/archai>

- NAS for non-experts
 - Turnkey experimentation platform
 - MIT license
- High performance PyTorch code base
- Ease of algorithm development
 - Object-oriented model definition
 - Unified abstractions for training and evaluation
 - New algorithms can be written in a few lines of code
 - Easily mix and match existing algorithm aspects
 - Easily implement both forward and backward search
 - Algorithm-agnostic pareto-front generation
 - Easily add hardware-specific constraints like memory, inference time, flops etc.
- Efficient experiment management for reproducibility and fair comparison
 - Flexible configuration system
 - Structured logging
 - Metrics management and logging
 - Declarative experimentation
 - Declarative support for wide variety of datasets
 - Custom dataset support
 - Unified final training procedure for searched models
